The column  $l_x$  shows, for each sex, the number of persons who would survive to exact age  $x$  out of 10,000 born who were subject throughout their lives to the recorded age death rates of the period. Column  ${}^o e_x$  is the 'expectation of life', that is the average remaining lifetime for a person who survives at the beginning of the indicated age interval, if likewise subject to those death rates.
